1. (20 pts total) *Solve the following recurrence relations using any of the following methods: unrolling, tail recursion, recurrence tree (include tree diagram), or expansion. Each case, show your work.*

(a)  $T(n) = T(n - 4) + Cn$  if  $n > 1$ , and  $T(n) = C$  otherwise

(b)  $T(n) = 3T(n - 2) + 1$  if  $n > 1$ , and  $T(n) = 3$  otherwise

---

(c)  $T(n) = T(n-1) + 2^n$  if  $n > 1$ , and  $T(1) = 3$

(d)  $T(n) = T(n^{1/2}) + 1$  if  $n > 2$ , and  $T(n) = 0$  otherwise

2. (10 pts) *Consider the following function:*

```
def foo(n) {  
    if (n > 1) {  
        print( ''hello'' )  
        foo(n/3)  
        foo(n/3)  
        foo(n/3)  
    }  
}
```

*In terms of the input  $n$ , determine how many times is “hello” printed. Write down a recurrence and solve using the Master method.*

3. (30 pts) *Professor Flitwick asks you to help him with some arrays that are slumped. An array  $A$  is slumped if  $A[1..i]$  has the property that, for some  $C > 0$ ,  $A[j+1] = A[j] - C$  for  $1 \leq j < i$ , and  $A[i..n]$  has the property that, for some  $D > 0$  where  $C \neq D$ ,  $A[j+1] = A[j] + D$  for  $i \leq j < n$ . Using his wand, Flitwick writes the following slumped array on the board  $A = [7, 3, -1, -5, 0, 10, 15, 20, 25]$ , as an example.*
- (a) *Flitwick found that one of his slumped arrays had an identical adjacent value (i.e.,  $A[j] = A[j+1]$ ) and no longer trusts any of his slumped arrays. Write a recursive algorithm that takes asymptotically sub-linear time to ensure that there are no identical adjacent elements in  $A$ .*

- (b) *Prove that your algorithm is correct. (Hint: prove that your algorithm's correctness follows from the correctness of another correct algorithm we already know.)*

- (c) *Now consider the multi-slumped generalization, in which the array contains  $k$  local minima, i.e., it contains  $k$  subarrays, each of which is itself a slumped array. Let  $k = 2$  and prove that your algorithm can fail on such an input.*

- (d) *Suppose that  $k = 2$  and we can guarantee that neither local minimum is closer than  $n/3$  positions to the middle of the array, and that the “joining point” of the two singly-slumped subarrays lays in the middle third of the array. Now write an algorithm that tests  $A$  for identical adjacent values in sublinear time. Prove that your algorithm is correct, give a recurrence relation for its running time, and solve for its asymptotic behavior.*
